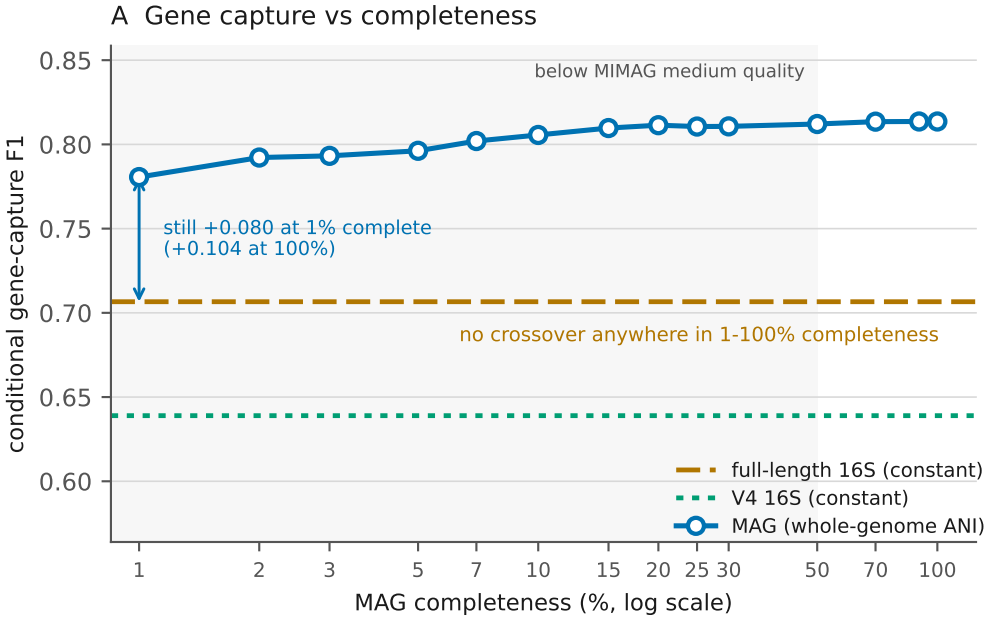
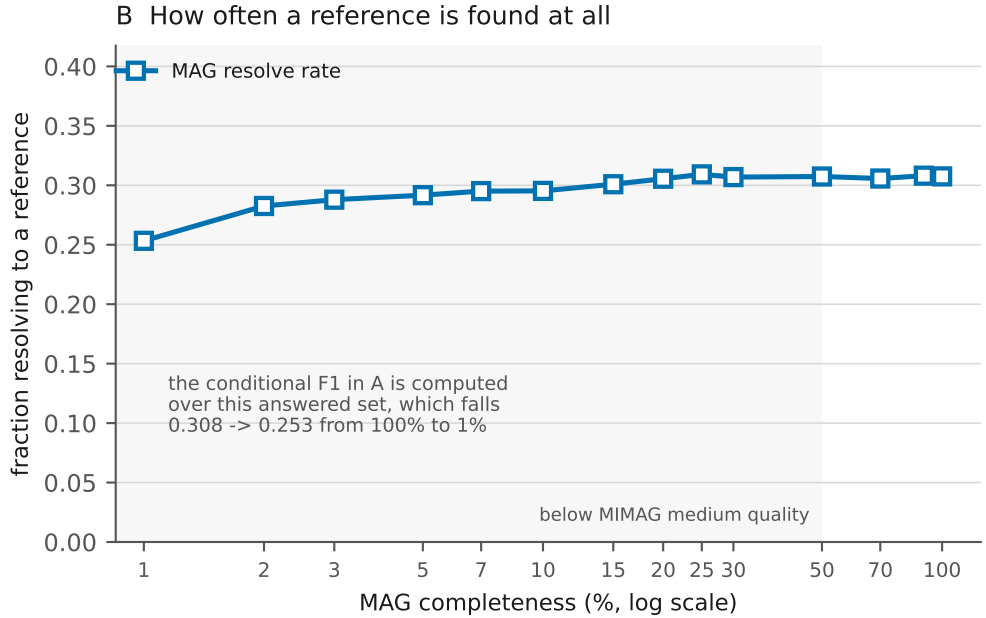
MAG gene capture holds far below any usable MAG quality threshold





9,997 BV-BRC panel genomes per completeness tier, 0% contamination, self-exclusion (source genome, source taxon and every >=95-ANI hit removed). The amplicon constants are paired means over the matched organisms at each tier (n=1,260-1,580), so the reference moves only with the matched set. The shaded region is below MIMAG's medium-quality floor of 50% completeness -- a MAG study would discard every bin left of it, and gene capture is still above both amplicon constants there.
